

# Statements and expressions

Victor Eijkhout, Susan Lindsey

Fall 2019

# Basics

# Two kinds of files

In programming you have two kinds of files:

- *source files*, which are understandable to you, and which you create with an editor such as `vi` or `emacs`; and
- *binary files*, which are understandable to the computer, and unreadable to you.

Your source files are translated to binary by a compiler.

# Exercise 1

Make a file `zero.cc` with the following lines:

```
#include <iostream>
using std::cout;
using std::endl;

int main() {
    return 0;
}
```

and compile it. Intel compiler:

```
icpc -o zeroprogram zero.cc
```

Run this program (it gives no output):

```
./zeroprogram
```

# Compile line

- `icpc` : compiler. Alternative: use `g++` or `clang++`
- `-o zeroprogram` : output into a binary name of your choosing
- `zero.cc` : your source file.

## Exercise 2

Add this line:

```
cout << "Hello world!" << endl;
```

(copying from the pdf file is dangerous! please type it yourself)

Compile and run again.

(Did you indent the 'hello world' line? Did your editor help you with the indentation?)

# C++ versions

- The compiler by default uses C++98.
- This course explains C++17. You need tell your compiler about this.
- On `isp.tacc.utexas.edu` 'icpc' uses this by default.
- On your own machine you need to do

```
g++ -std=c++17 [other options]
```

or

```
alias g++='g++ -std=c++17'
```

# Review quiz 1

True or false?

1. The programmer only writes source files, no binaries.
2. The computer only executes binary files, no human-readable files.

# Errors

There are two types of errors that your program can have:

1. *Syntax* or *compile-time* errors: these arise if what you write is not according to the language specification. The compiler catches these errors, and it refuses to produce a binary file.
2. *Run-time* errors: these arise if your code is syntactically correct, and the compiler has produced an executable, but the program does not behave the way you intended or foresaw. Examples are divide-by-zero or indexing outside the bounds of an array.

# File names

File names can have extensions: the part after the dot.

- `program.cxx` or `program.cc` are typical extensions for C++ sources.
- `program.cpp` is also used, but there is a possible confusion with 'C PreProcessor'.
- Using `program` without extension usually indicates an executable.

# Statements

# Program statements

- A program contains statements, each terminated by a semicolon.
- 'Curly braces' can enclose multiple statements.
- A statement can correspond to some action when the program is executed.
- Some statements are definitions, of data or of possible actions.
- Comments are 'Note to self', short:

```
cout << "Hello world" << endl; // say hi!
```

and arbitrary:

```
cout << /* we are now going  
        to say hello  
        */ "Hello!" << /* with newline: */ endl;
```

## Exercise 3

Take the 'hello world' program you wrote above, and duplicate the hello-line. Compile and run.

Does it make a difference whether you have the two hellos on the same line or on different lines?

Experiment with other changes to the layout of your source. Find at least one change that leads to a compiler error. Can you relate the message to the error?

# Fixed elements

You see that certain parts of your program are inviolable:

- There are keywords such as `return` or `cout`; you can not change their definition.
- Curly braces and parentheses need to be matched.
- There has to be a `main` keyword.
- The `iostream` and `std` are usually needed.

## Exercise 4

Experiment with the `cout` statement. Replace the string by a number or a mathematical expression. Can you guess how to print more than one thing, for instance:

- the string `One third is,` and
- the result of the computation `1/3,`

with the same `cout` statement?

# Variables

# What's a variable?

Programs usually contain data, which is stored in a variable.

A variable has

- a datatype,
- a name, and
- a value.

These are defined in a variable declaration and/or variable assignment.

# Typical variable lifetime

```
int i,j; // declaration
i = 5;   // set a value
i = 6;   // set a new value
j = i+1; // use the value of i
i = 8;   // change the value of i
         // but this doesn't affect j:
         // it is still 7.
```

# Variable names

- A variable name has to start with a letter;
- a name can contains letters and digits, but not most special characters, except for the underscore.
- For letters it matters whether you use upper or lowercase: the language is case sensitive.
- Words such as *main* or *return* are reserved words.
- Usually *i* and *j* are not the best variable names: use *row* and *column*, or other meaningful names, instead.

# Declaration

There are a couple of ways to make the connection between a name and a type. Here is a simple variable declaration, which establishes the name and the type:

```
int n;  
float x;  
int n1,n2;  
double re_part,im_part;
```

# Where do declarations go?

Declarations can go pretty much anywhere in your program, but they need to come before the first use of the variable.

Note: it is legal to define a variable before the main program but that's not a good idea. Please only declare *inside* main (or inside a function et cetera).

## Review quiz 2

Which of the following are legal variable names?

1. `mainprogram`
2. `main`
3. `Main`
4. `1forall`
5. `one4all`
6. `one_for_all`
7. `onefor{all}`.

# Datatypes

Variables come in different types;

- We call a variable of type `int`, `float`, `double` a numerical variable.
- *Complex numbers* will be discussed later.
- For characters: `char`. Strings are complicated; see later.
- Truth values: `bool`
- You can make your own types. Later.

# Assignments

# Assignment

Once you have declared a variable, you need to establish a value. This is done in an assignment statement. After the above declarations, the following are legitimate assignments:

```
n = 3;  
x = 1.5;  
n1 = 7; n2 = n1 * 3;
```

Variable of the left-hand side gets value of the right-hand side.

You see that you can assign both a simple value or an expression.

# Assignments

A variable can be given a value more than once. The following sequence of statements is a legitimate part of a program:

```
int n;  
n = 3;  
n = 2*n + 5;  
n = 3*n + 7;
```

These are not math equations: variable on the lhs gets the value of the rhs.

# Special forms

Update:

```
x = x+2; y = y/3;  
// can be written as  
x += 2; y /= 3;
```

Integer add/subtract one:

```
i++; j--; /* same as: */ i=i+1; j=j-1;
```

## Review quiz 3

Which of the following are legal? If they are, what is their meaning?

1.  $n = n;$
2.  $n = 2n;$
3.  $n = n2;$
4.  $n = 2*k;$
5.  $n/2 = k;$
6.  $n /= k;$

# Initialization syntax

There are two ways of initializing a variable

```
int i = 5;  
int j{6};
```

Note that writing

```
int i;  
i = 7;
```

is not an initialization: it's a declaration followed by an assignment.

If you declare a variable but not initialize, you can not count on its value being anything, in particular not zero. Such implicit initialization is often omitted for performance reasons.

## Review quiz 4

```
#include <iostream>
using std::cout;
using std::endl;
int main() {
    int i;
    int j = i+1;
    cout << j << endl;
    return 0;
}
```

What happens?

1. Compiler error
2. Output: 1
3. Output is undefined
4. Error message during running the program.

# Terminal input

To make a program run dynamic, you can set starting values from keyboard input. For this, use `cin`, which takes keyboard input and puts it in a numerical (or string) variable.

```
// add at the top of your program:  
using std::cin;
```

```
// then in your main:  
int i;  
cin >> i;
```

# Floating point constants

- Default: `double`
- Float: `3.14f` or `3.14F`
- Long double: `1.22l` or `1.22L`.

# Warning: floating point arithmetic

Floating point arithmetic is full of pitfalls.

- Don't count on  $3 \times (1./3)$  being exactly 1.
- Not even associative.

(See Eijkhout, Introduction to High Performance Computing, chapter 3.)

# Truth values

So far you have seen integer and real variables. There are also boolean values which represent truth values. There are only two values: `true` and `false`.

```
bool found{false};  
found = true;
```

# Quick intro to strings

- Add the following at the top of your file:

```
#include <string>  
using std::string;
```

- Declare string variables as

```
string name;
```

- And you can now `cin` and `cout` them.

# Input/Output

# Terminal output

You have already seen cout:

```
float x = 5;  
cout << "Here is the root: " << sqrt(x) << endl;
```

## Exercise 5

Write a program that asks for the user's first name, uses `cin` to read that, and prints something like `Hello, Susan!` in response.

What happens if you enter first and last name?

# Expressions

# Arithmetic expressions

- Expression looks pretty much like in math.  
With integers:  $2+3$   
with reals:  $3.2/7$
- Use parentheses to group  $25.1*(37+42/3.)$
- Careful with types.
- There is no 'power' operator: library functions.
- Modulus: %

# Math library calls

Math function in `cmath`:

```
#include <cmath>
.....
x = pow(3, .5);
```

For squaring, usually better to write `x*x` than `pow(x,2)`.

# Boolean expressions

We'll do that in the lecture on conditionals.

## Exercise 6

Write a program that :

- displays the message `Type a number,`
- accepts an integer number from you (use `cin`),
- makes another variable that is three times that integer plus one,
- and then prints out the second variable.

# Turn it in!

- If you have compiled your program, do:

```
sdstest3np1 yourprogram.cc
```

where 'yourprogram.cc' stands for the name of your source file.

- Is it reporting that your program is correct? If so, do:

```
sdstest3np1 -s yourprogram.cc
```

where the -s flag stands for 'submit'.

# Conversion and casting

Real to integer: round down:

```
double x,y; x = .... ; y = .... ;  
int i; i = x+y;
```

Dangerous:

```
int i,j; i = ... ; j = ... ;  
double x ; x = 1+i/j;
```

The fraction is executed as integer division.

For floating point result do:

$(1.*i)/j$

## Optional exercise 7

Write a program that asks for two integer numbers  $n_1, n_2$ .

- Assign the integer ratio  $n_1/n_2$  to an integer variable.
- Can you use this variable to compute the modulus

$$n_1 \bmod n_2$$

(without using the % modulus operator!)

Print out the value you get.

- Also print out the result from using the modulus operator: %.
- Investigate the behaviour of your program for negative inputs.  
Do you get what you were expecting?

## Optional exercise 8

Write two programs, one that reads a temperature in Centigrade and converts to Fahrenheit, and one that does the opposite conversion.

$$C = (F - 32) \cdot 5/9, \quad F = 9/5 C + 32$$

Check your program for the freezing and boiling point of water. (Do you know the temperature where Celsius and Fahrenheit are the same?)

Can you use Unix pipes to make one accept the output of the other?

# Review quiz 5

True or false?

1. Within a certain range, all integers are available as values of an integer variable.
2. Within a certain range, all real numbers are available as values of a float variable.
3.  $5(7+2)$  is equivalent to 45.
4.  $1--1$  is equivalent to zero.
5. `int i = 5/3.;` The variable `i` is 2.
6. `float x = 2/3;` The variable `x` is approximately 0.6667.
